A diagnostic for DeFi teams navigating liquidity fragmentation and network expansion.

Where does your product sit?

Most DeFi products were built for a single network. Users, liquidity, and activity have moved on. This diagnostic helps you assess how exposed your product is to cross-network fragmentation, and where the biggest gaps are.

Four questions for your team.

Score each honestly. If you can't answer one confidently, that's a signal in itself.

01

How many networks can your users transact on today?

If your product is live on 1 or 2 networks, your addressable market is a fraction of what it could be. Over 50 networks have active DeFi users, and that number is growing every quarter.

02

Where does your liquidity come from?

If you're sourcing liquidity from pools on a single network, your users are getting worse prices than they should. Deeper capital exists elsewhere, but your product can't reach it.

03

How long would it take to deploy on a new network?

If the answer is months of engineering, you're falling behind teams that can expand in under a week. Every new network launch is a window, and most close fast.

04

Who maintains your cross-network infrastructure?

If the answer is your own team, you're spending engineering cycles on plumbing instead of product. The maintenance burden compounds with every network you add.

If you scored well on all four, you're ahead of most teams. If not, the next page walks through your options.

YOUR OPTIONS

Every DeFi team going cross-network faces the same three paths. Each comes with real tradeoffs in cost, control, speed, and maintenance.

01

Build it yourself

+ Full control over routing and execution logic.

- 3 to 6 months to build. Heavy maintenance. Every new network is a new project.

02

Use messaging infra

+ Handles data and asset transfer across networks.

- Your team still owns execution logic, failure handling, and liquidity sourcing.

03

Integrate an execution system

+ Cross-network execution, liquidity, and recovery handled for you.

- Less granular control. You're trusting the provider's infrastructure.

The honest truth:

Most teams start with Path 1, realize the maintenance burden after 3 to 6 months, and migrate toward Path 2 or 3. The question isn't which path is best. It's which one matches your team's resources, timeline, and product priorities right now.

How to evaluate any cross-network solution.

Use these criteria in your next architecture review. They apply regardless of which path you take.

Network coverage	How many networks, and does it include both EVM and non-EVM? A solution that only covers EVM leaves out some of the fastest-growing ecosystems.
Execution reliability	What happens when a route fails mid-transaction? Does the system recover, or does your user file a support ticket? Ask for failure rate data.
Liquidity depth	Does it access liquidity across networks, or only local pools? The difference shows up directly in execution prices for your users.
Integration effort	Weeks or months? Ask for a realistic timeline including testing, not just 'drop in the SDK.' Factor in ongoing maintenance, not just initial setup.
Maintenance burden	Does your team manage ongoing infrastructure, or does the provider handle it? Every network upgrade, token listing, and route change is a maintenance event.

WHERE IT'S HEADING

Three shifts redefining how DeFi products go cross-network.

01

Intent-based execution is replacing manual routing.

Users express what they want. A Solver figures out the best way to execute it. No bridge selection, no network switching, no manual steps.

02

Liquidity is being unified, not duplicated.

Instead of bootstrapping separate pools on every network, execution systems coordinate access to liquidity wherever it already exists.

03

Cross-network is becoming infrastructure, not a feature.

The teams building the best DeFi products in 2026 aren't building cross-network infrastructure. They're integrating it and focusing on what makes their product different.

This is what we built at SODAX.

SODAX is execution infrastructure for cross-network DeFi. One SDK integration gives your product access to unified liquidity, lending, borrowing, yield, and settlement across 18 networks.

18	16	20	<30s	~1 wk
Networks EVM + non-EVM	Partner integrations live	Money market assets	Cross-network execution	Typical integration timeline

Complex cross-network flows are handled at the infrastructure level. Your team controls the UX. SODAX handles routing, settlement, and failure recovery behind the scenes.

Infrastructure for modern money. Cross-network technology since 2017. Audited infrastructure. Compatible with LayerZero.
